PAPER

Please find below and/or attached an Office communication concerning this application or proceeding.

The time period for reply, if any, is set in the attached communication.

DETAILED ACTION

The response dated 11-14-08 is acknowledged.

Claims included in the prosecution are 1-21, 23, 30, 40-42 and 47-71.

Claim Rejections - 35 USC § 103

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. Claims 1-21, 23, 30, 40-42 and 47-71 are rejected under 35 U.S.C. 103(a) as being unpatentable over WO 99/13816 in combination with Tardi (US 2003/0124181).

WO 99 discloses a method of loading camptothecins using a pH gradient at a higher temperature, which is same as instant method. The lipids used include DSPC, cholesterol and phosphatidyl glycerols. WO on page 12, line 20 through page 13 line 2 teaches more than 5 mM buffers such as citric acid, ammonium citrate and ammonium sulfate and the temperature conditions. WO discusses alkyl amines and various ammonium salts in the paragraph bridging pages 14 and 15. The lipid to camptothecin ratios are from 5:1 to 100:1 (abstract, pages 10-15, 18, Example 2 and claims). Although in examples, WO uses citric acid at 50 mM concentration, in view of WO's teachings that it can be higher than 5 mM, it would have been obvious to one of ordinary skill in the art to vary the molarity up to 60 mM with the expectation of obtaining

Art Unit: 1612

the best possible results. What is lacking in WO is the loading of active agents other than camptothecins, such as claimed anthracyclines.

Tardi while disclosing liposomal compositions containing various active agents teaches that therapeutic agents which can be loaded using pH gradients comprise one more ionizable moiety such that the neutral form of the ionizable moiety allows the drug to cross the liposome membrane and conversion of the moiety to charged form causes the drug to remain encapsulated within the liposomes. Tardi teaches that the ionizable moieties comprise amine, carboxylic acid and hydroxyl groups. Among the active agents taught by Tardi are camptothecins, vinca alkaloids such as vinblastine, and vincristine and anthracycline antibiotics such as doxorubicin (0080-0081). Tardi further teaches dehydrating the liposomes and the use of cryoprotectants (claims).

The use of the liposomes of WO to load active agents such as anthracycline antibiotics would have been obvious to one of ordinary skill in the art since Tardi teaches that any ionizable active agent having an amine, carboxyl and hydroxyl functional groups can be loaded using pH gradients and those compounds include camptothecins and anthracyclines.

WO does not teach the use of sphingomyelin in the preparation of the liposomes, since it is a commonly used lipid in the liposome formations, it would have been obvious to one of ordinary skill in the art to use this lipid with a reasonable expectation of success.

Applicant's arguments have been fully considered, but are not persuasive. Applicant mainly focuses on Tardi's teachings and argues that Tardi does not teach the preparation of any liposomes using the quenching step. Further according to applicant,

Art Unit: 1612

the final liposomes prepared by Tardi maintain a low pH in the internal aqueous space that helps keep the drug loaded in the liposomes. These arguments are not persuasive. The examiner recognizes the method of Tardi is slightly different from the method of WO. However, both methods are directed to loading of the ionizable drugs using pH gradients and WO teaches such a step. Tardi is combined since WO does not teach drugs other than camptothecins and Tardi teaches the equivalency between camptothecins and claimed anthracyclines and vinca alkaloids. Since all of them are ionizable compounds, one of ordinary skill in the art would be motivated to use the method of WO to load even anthracyclines and vinca alkaloids. Applicant has not shown any unexpected results by using the method taught by WO for loading these drugs.

Applicant's arguments that the inclusion of claim 7 is an error are not persuasive since sphingomyelin is known in the art as a liposome forming lipid. Applicant's arguments that the inclusion of claim 49 is an error are not persuasive since the prior art on record clearly indicates that methylamine is a commonly used base in liposome technology. Applicant's arguments that the inclusion of claims 52-57 is an error are not persuasive since Tardi clearly shows the use of cryoprotectants (claims).

3. Claims 1-21, 23, 30, 40-42 and 47-71 are rejected under 35 U.S.C. 103(a) as being unpatentable over EP 0 719 546 in view of WO 99/13816.

EP discloses a method of loading active agents using a pH gradient at a higher temperature. The method is applicable to several anti-cancer agents such as doxorubicin, vincristine, purine or pyrimidine compounds, antibiotics and others. The lipids used are EPC and cholesterol. Other phospholipids suggested are DSPC, DPPC,

Art Unit: 1612

DMPC and DAPC. Although in examples, EP teaches the loading of doxorubicin at a higher pH than the interior pH of the liposomes, on col. 20, lines 44-49 it teaches that pH gradients can be established with a second external medium of relatively acidic or basic pH. Therefore, it would have been obvious to one of ordinary skill in the art to load an active agent at an acidic medium and then relative to the liposome interior and then change the pH of the exterior to basic pH such that the active agent remains entrapped. Although EP does not teach cooling of the solution (step c), such a step would have been obvious to one of ordinary skill in the art since WO such a step. Although EP does not disclose the use of phosphatidylglycerol in the liposomes, since it is the commonly used negatively charged lipid to provide negative charge to the liposomes, it would have been obvious to one of ordinary skill in the art to include this phospholipid with a reasonable expectation of success. One of ordinary skill in the art would be motivated further to include this lipid since WO which is discussed below advocates the use of this lipid in similar active agent loading method.

Applicant's arguments have been fully considered, but are not persuasive.

Applicant argues that camptothecin compounds differ significantly in chemical structure from agents that were loaded in EP. This argument is not persuasive since both are ionizable compounds. Furthermore, applicants themselves state on page 15, line 19 that camptothecins can also be used. Applicants argue that the examiner has not provided any evidence to support his conclusion that it would have been obvious to one of ordinary skill in the art to load an active agent at an acidic medium and then relative to the liposome interior and then change the pH of the exterior to basic pH such that the

Art Unit: 1612

active agent remains entrapped. This argument is not persuasive since as pointed out above, EP teaches on col. 20, lines 44-49 that pH gradients can be established with a second external medium of relatively acidic or **basic pH**. Since it is a gradient and since the external medium as taught by EP is basic pH, the inner acidic pH is implicit.

Furthermore, the gradient with a basic external medium is taught also by WO.

Therefore, no affidavit or declaration by the examiner as demanded by applicants is necessary. In response to applicant's arguments that the examiner has not provided any evidence to support the conclusion about the use of phosphatidylglycerol, the examiner points out to col. 13, line 4 of EP which teaches the use of phosphatidylglycerol. Therefore, no affidavit or declaration by the examiner as demanded by applicants is necessary.

Applicant's arguments that the inclusion of claim 7 is an error are not persuasive since sphingomyelin is known in the art as a liposome forming lipid as the prior art on record clearly supports this fact. Applicant's arguments that the inclusion of claim 49 is an error are not persuasive since the prior art on record clearly indicates that methylamine is a commonly used base in liposome technology. Applicant's arguments that the inclusion of claims 52-57 is an error are not persuasive since the prior art on record clearly shows the use of cryoprotectants.

4. Claims 7 and 49 are rejected under 35 U.S.C. 103(a) as being unpatentable over WO 99/13816 in combination with Tardi OR over EP 0 719 546 in combination with WO as set forth above, further in view of Webb (5,814,335) of record.

The teachings of WO, Tardi and EP have been discussed above. What is lacking in these references is the use of sphingomyelin as the liposome-forming lipid. The use of sphingomyelin however, would have been obvious to one of ordinary skill in the art since Webb teaches that sphingomyelin containing liposomes are stable and have extended circulation time (abstract). Neither EP nor WO teaches the change of the pH of the external medium by using methylamine. The use of methylamine to change the pH of the external medium would have been obvious to one of ordinary skill in the art with a reasonable expectation of success since Webb teaches the creation of pH gradient using methylamine (columns 7 and 8).

Applicant's arguments have been fully considered, but are not persuasive. The examiner has already addressed applicant's arguments regarding WO and Tardi. Applicant provides no specific arguments regarding the use of sphingomyelin taught by Webb. Applicant argues that Webb uses methylamine for a significantly different function. This argument is not persuasive since methylamine is a base which is commonly used for changing the pH while loading drugs into the liposomes and it is within the skill of the art to use any base including methylamine with the expectation of obtaining similar pH changes and applicant has not shown any unexpected results by using methylamine.

5. Claims 52-57 are rejected under 35 U.S.C. 103(a) as being unpatentable over WO 99/13816 in combination with Tardi (US 2003/0124181) OR over EP 0 719 546 in combination with WO as set forth above, further in view of Clerc (5,939,096).

The teachings of Tardi, EP and WO have been discussed above.

Clerc while disclosing a method of drug loading by pH gradient teaches that liposomes can be dehydrated for storage in the presence of cryoprotectant sugars (col. 8, lines 9-15). It would have been obvious to one of ordinary skill in the art to use cryoprotectants and dehydrate liposomes since they can be stored in that state as taught by Clerc.

Applicant's arguments have been fully considered, but are not persuasive. The examiner has already addressed applicant's arguments regarding WO and Tardi. Applicant provides no specific arguments regarding the use of cryoprotectants taught by Clerc.

Double Patenting

6. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. A nonstatutory obviousness-type double patenting rejection is appropriate where the conflicting claims are not identical, but at least one examined application claim is not patentably distinct from the reference claim(s) because the examined application claim is either anticipated by, or would have been obvious over, the reference claim(s). See, e.g., *In re Berg*, 140 F.3d 1428, 46 USPQ2d 1226 (Fed. Cir. 1998); *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422 F.2d 438, 164 USPQ 619 (CCPA 1970); and *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) or 1.321(d) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent either is shown to be commonly owned with this application, or claims an invention made as a result of activities undertaken within the scope of a joint research agreement.

Art Unit: 1612

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

7. Claims 1-23, 30, 40-42 and 47-71 are rejected on the ground of nonstatutory obviousness-type double patenting as being unpatentable over claims 30-31 and 35-64 of U.S. Patent No. 6,740,335 in combination with Tardi (US 2003/0124181). Although the conflicting claims are not identical, they are not patentably distinct from each other because both patented claims and instant claims are drawn to the process of loading agents using pH gradients. Instant claims are generic with respect to the active agents loaded whereas the patented claims recite specific camptothecin compound. However, it would have been obvious to one of ordinary skill in the art to load any active agent using a pH gradient with a reasonable expectation of success since Tardi teaches that any ionizable active agent having an amine, carboxyl and hydroxyl functional groups can be loaded using pH gradients and those compounds include camptothecins, anthracyclines and vinca alkaloids. Patented claims do not recite the concentration of the acid while loading the active agent and instant mM amounts therefore, are deemed to be anticipated by the claims in the patent.

Applicant's arguments have been fully considered, but are not persuasive. The essence of applicant's arguments is that WO 99/13816 is a counter part of US 6,740,335 and therefore, the same arguments as above are applicable. The examiner has already addressed those arguments. The rejection therefore, is maintained.

In view of the amendment to the claims in the copending application, the double patenting rejection over the claims in 10/723,610 is withdrawn.

Art Unit: 1612

8. THIS ACTION IS MADE FINAL. Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire **THREE MONTHS** from the mailing date of this action. In the event a first reply is filed within **TWO MONTHS** of the mailing date of this final action and the advisory action is not mailed until after the end of the **THREE-MONTH** shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than **SIX MONTHS** from the mailing date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Gollamudi S. Kishore, Ph.D whose telephone number is (571) 272-0598. The examiner can normally be reached on 6:30 AM- 4 PM, alternate Friday off.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Krass Frederick can be reached on (571) 272-0580. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.
